Subject: NJ DEP Data Report #7: Non-targeted Analysis of PFAS in Water Samples Collected from Wells with Point of Entry Treatment

Dear Mr. Kloo:

I am pleased to provide you with the attached laboratory report that includes non-targeted analysis (NTA) results for per- and polyfluoroalkyl substance (PFAS) in water samples collected from wells to evaluate the effectiveness of Granular Activated Carbon (GAC) or Ion Exchange Resin (at one location) Point of Entry Treatment Systems (POETs). This is the seventh in a series of reports prepared as a part of EPA Office of Research and Development's (ORD) collaboration with the New Jersey Department of Environmental Protection (NJ DEP) and EPA Region 2 on the study, "Detection, Evaluation, and Assignment of Multiple Poly- and Perfluoroalkyl Substances (PFAS) in Environmental Media from an Industrialized Area of New Jersey."

It is our understanding that this study was designed to help NJ DEP in their ongoing investigation into the presence of PFAS in the environment near manufacturing facilities of interest. This study relates to our research capabilities and interests applying targeted and non-targeted analysis methods for discovery of the nature and extent of PFAS environmental occurrence that may be potentially associated with industrial releases. EPA continues to develop analytical methods for many PFAS compounds in various media including some of those included in this report. We are providing the results of our analysis as they become available.

In this report, we provide tentative identification and semi-quantitative analytical results for 24 PFAS. We do not interpret exposure or risk from any reported values. EPA does not currently have health-based standards, toxicity factors, or associated risk levels for PFAS, other than perfluorooctanoic acid (PFOA), perfluorooctane sulfonate (PFOS), and perfluorobutanesulfonic acid (PFBS). While the data provided in the attached report indicate the presence of PFAS in the water samples, we do not have sufficient information to offer interpretations related to human or environmental exposure and risk.

1

Thank you for inviting us to be part of this effort that helps to further both EPA's and New Jersey's understanding of an important issue in the state. This is just one of many Agency efforts that demonstrates EPA's commitment to cooperative federalism.

If you have any questions or concerns, do not hesitate to contact me at (919) 541-2107 or via email at Watkins.tim@epa.gov. I look forward to our continued work together.

Sincerely,

Timothy H Watkins

Timothy H. Watkins

Detection, Evaluation, and Assignment of PFAS in Environmental Media from an Industrialized Area of New Jersey

Laboratory Data Report #7: Non-targeted Analysis of PFAS in Water Samples Collected from Wells with Point of Entry Treatment

Background. This report stems from a collaborative study with EPA ORD, EPA Region 2, and NJ DEP entitled "Detection, Evaluation, and Assignment of Multiple Poly- and Perfluoroalkyl Substances (PFAS) in Environmental Media from an Industrialized Area of New Jersey." NJ DEP assumed responsibility for the collection of samples and their shipment to the ORD laboratory. ORD was responsible for sample extraction and analysis of PFAS. Preparation of this report involved many from ORD assuming various roles and responsibilities (Table 1).

Table 1. EPA Office of Research and Development Lab Analysis and Report Team.

Responsibility	Personnel
ORD Principal Investigators	Andy Lindstrom, Mark Strynar, John Washington
Laboratory chemistry	James McCord
Quality Assurance Review	Libby Nessley, Sania Tong Argao
Management coordination and review	Kate Sullivan, Myriam Medina-Vera, Tim Buckley
Report preparation	Kate Sullivan

This 7th report includes non-targeted analysis (NTA) results for 24 water samples collected at three points across the treatment process of 6 wells installed with Granular Activated Carbon (GAC) or Ion Exchange Resin (IER; at one location) Point of Entry Treatment Systems (POETs). Sample collection was the responsibility of NJ DEP and occurred September 5, 2019. Samples were shipped to and received by ORD on September 6, 2019. The samples were analyzed for PFAS under the direction of Dr. James McCord at ORD's laboratory in Research Triangle Park, NC.

The current data report provides a simple representation and summary of the NTA results. Therefore, the description of methods and quality assurance are brief and high-level. Additional reports and/or publications are being developed that will include a more detailed description of methods, quality assurance analyses, and statistical/geospatial interpretation of the project data. As study partners/collaborators, we anticipate that NJ DEP and EPA Region 2 scientists will assist in these additional reports and publications.

Methods in Brief. Water samples were analyzed by ultra-performance liquid chromatography mass spectrometry (UPLC-MS) using methods described within our Laboratory Quality

Assurance Project Plan[1,2] and McCord *et al.* 2019[3]. In brief, water samples (500 mL) were filtered and then extracted using a WAX solid phase extraction cartridge. PFAS was removed from the cartridge in methanol and the volume reduced to 1 mL under a gentle stream of dry nitrogen. An aliquot of the 1 mL concentrated sample was injected into a Thermo Fisher Scientific™ Vanquish™ ultra-performance liquid chromatograph (UPLC) coupled to a Thermo Fisher Scientific™ Orbitrap Fusion™ MS. Samples were not diluted.

PFAS were analyzed using NTA methods. NTA provides two important measurements. The first is a tentative identification of PFAS compounds detected in the sample based on a combination of mass spectral data along with patterns of fragmentation compared to on-line and in-house mass-spectral libraries. Analytes in each sample and process blank were identified to various levels of confidence depending on the combined evidence from manual examination of MS/MS fragmentation spectra and/or comparison with mass spectral libraries.

The second measurement is an indication of the relative abundance of the PFAS present in the sample. The MS detector provides integrated peak areas for the chromatogram of the compound mass (+/- 5 ppm) at the specified retention time. The peak area counts are proportional to the mass of PFAS in the sample. Since the sample and injection volume are held constant, the peak area counts are also proportional to concentration, although the relationship varies based on compound.

It is important to understand how NTA results differ from those produced during routine laboratory targeted analysis. Without a standard curve to calibrate the relationship between peak area and a mass or concentration value, the peak area counts alone should be considered a semi-quantitative indicator of relative abundance. Analyte peak areas can be compared between samples in a sample set to obtain relative concentrations but cannot be directly compared between analytes. Our experience indicates that measured abundances for PFAS are four to six orders of magnitude higher than the ppt concentration (e.g. 1e7 ~ 100 ppt) not accounting for dilutions during sample preparation. Peak area counts are expected to have much greater inherent sampling and analytical variability, which may become evident in reproducibility assessments. For example, it is possible for field duplicates to differ by two or three-fold or more, and laboratory replicates to have greater variability than typically observed in routine laboratory analysis. Any application of NTA results should consider this inherently greater uncertainty.

The NTA data generated by UPLC/MS were considered as a "detect" when acceptable chromatographic peaks and spectra were evident. Samples without a detectable peak are reported as "ND" or not detected. Samples with detected analytes were further screened to determine the

[3]McCord, J., Strynar, M. Identifying Per- and Polyfluorinated Chemical Species with a Combined Targeted and Non-Targeted-Screening High-Resolution Mass Spectrometry Workflow. *J. Vis. Exp.* (146), e59142, doi:10.3791/59142 (2019). https://www.jove.com/video/59142/identifying-per-polyfluorinated-chemical-species-with-combined

reporting limit (RL) that accounts for contamination that may have occurred during sampling and analysis including field, laboratory, and instrument blanks. The RL was established for each compound by statistical analysis of the combined laboratory and field blanks according to Equation 1. Sample values less than this threshold are reported as "<RL".

Equation 1. Reporting Limit (RL) =Average [Field and Laboratory blanks] + 3x STD [blanks].

Because of the particular interest in the chloro-perfluoro-polyether-carboxylate congeners (ClPFPECA) identified in soil and vegetation samples (Report #2 dated March 8, 2019), we reanalyzed the samples to provide an additional semiquantitative estimate of their concentration (ng/L). Since there are no standards for ClPFPECA congeners, an estimate of their concentration is derived from the MS response for two stable isotope-labeled compounds ($^{13}C_4$-labeled perfluorooctane sulfonate (M4PFOS) and $^{13}C_4$-labeled perfluorononoic acid (M5PFNA) of known concentration to serve as an internal standard. The concentration of ClPFPECA was estimated proportional to its peak area assuming the same instrument response as the labeled PFAS as shown in Equation 2.

Equation 2.
$$ClPFPECA_{Conc} = \frac{ClPFPECA_{PA} \times C^{13}PFOS\_OA_{Conc}}{C^{13}PFOS\_OA_{PA}}$$

Where:

$ClPFPECA_{Conc}$ is the semi-quantified ClPFPECA concentration (ng/L)

$ClPFPECA_{PA}$ is the ClPFPECA peak area

C^{13}-$PFOS\_OA_{Conc}$ is the known concentration of labeled PFOS (or PFNA) after spiking into the sample (ng/L)

C^{13}-$PFOS\_OA_{PA}$ is the peak area of the labeled PFOS or PFOA

ClPFPECA results are expressed as PFOS IS-based or PFNA IS-based concentration (ng/L). Our experience with PFAS suggests that this means of estimation is within an order of magnitude of the actual concentration.

Summary of Results

Compound Identification: Across all the water samples, we detected and tentatively identified 24 different PFAS listed in Table 2 by chemical formula, name, CAS registry number (CASRN), monoisotopic mass, and retention time, where available. Note that there are only 16 unique PFAS compounds in Table 2. Several of the primary compounds have one or more isomers that have the same intrinsic properties but are distinguished primarily by retention time. In many cases, isomer branching could be identified. PFAS compounds with CASRN registered in EPA's Comptox Chemistry Dashboard (https://comptox.epa.gov/dashboard) where additional information about these chemicals can be found (U.S. EPA CompTox, 2019)[4].

Abundance of Compounds: Table 3 provides peak area counts for well samples and various field blanks. The peak areas are superimposed on a heat map where gradations in color reflect seven classifications of peak area from low (non-detect and less than the reporting limit) to high

---

[4] U.S. EPA CompTox Chemistry Dashboard https://comptox.epa.gov/dashboard.

(>1,000,000). The heat map is useful in showing where PFAS "light-up" in terms of detection and high peak areas.

None of the PFAS compounds were detected at levels greater than the reporting limit in the field blanks, although a number of the blanks had detectable peak areas for many of the analytes. We report the relative percent difference (RPD) of the field duplicate pairs as a measure of reproducibility in the samples. The RPD of the sample pair PFPW007_INF and was 75% averaged for analytes greater than RL. The peak areas for this sample were consistently biased low relative to its duplicate, which may indicate a variation in the concentration factor between preparations. This affects non-targeted abundances, but not estimated concentrations based on internal standard correction. The RPD of the sample pair collected at PFPW017_INF averaged 16% and all analytes met the reproducibility goal of 50%.

A number of the analytes were found in the influent of many of the wells at various levels of abundance. After GAC or IER treatment, analyte abundance in effluents was considerably reduced or not detected. An exception to this trend was the effluent sample for PFPW010 where effluent levels exceeded the influent or mid-point levels for a few analytes. It is unclear whether detections associated with this sample are reflective of conditions at the POET effluent, the result of typical NTA abundance variation, or from contamination during sample collection/handling/processing. We could conduct targeted analysis on this sample if it would help to clarify this result, but additional analysis is not included in this report.

NTA analysis of the well water samples identified the presence of the congener series named Chloro-Perfluoro-Polyether-Carboxalate that were previously found in soils[5] (ClPFPECA, Chem. Ref. #21 in Table 3). Results of the semiquantitative analysis of ClPFPECA congeners conducted with internal standards are provided in Table 4. The generic structure of the ClPFPECA congeners is shown in Figure 1. Analysis of soils previously identified nine congeners with m and n varying from 0 to 3. This analysis of well samples analyzed for 6 congeners with m and n varying from 0 to 2.

Figure 1. Generic Structure of Chloro-Perfluoro-Polyether-Carboxylate (ClPFPECA).
Table 4 provides the Peak areas of 6 ClFPECA congeners and the estimated concentration of the 0,1 (ethyl, propyl) congener which accounted for 99% of the ClPFPECA quantified. Two of the congeners were not detected in samples. Since this was a separate analysis, the peak areas of ClPFPECA (Chem. Ref. #21) reported in Table 3 are not directly comparable to the peak areas reported in Table 4.

Table 4. Semi-Quantitation of Chloro-Perfluoro-Polyether-Carboxylate Congeners (ClPFPECA) in Water Samples. Concentration Values (ng/L) are Estimated Based on Labeled PFOS and PFNA Using Equation 2 Above.

Ethyl/Propyl Sample ID	Fully Integrated Peak Area						Estimated ClPFPECA(0,1) Concentration (ng/L)		
	Cl-PFPECA 1,0	Cl-PFPECA 2,0	Cl-PFPECA 0,1	Cl-PFPECA 1,1	Cl-PFPECA 2,1	Cl-PFPECA 0,2	as M4PFOS	as M5PFNA	Average
